Verilog HDL Operators

Verilog Operator	Name	Functional Group
[]	bit-select or part-select	
()	parenthesis	
!	logical negation	logical
~	negation	bit-wise
&	reduction AND	reduction
	reduction OR	reduction
~&	reduction NAND	reduction
~	reduction NOR	reduction
^	reduction XOR	reduction
~^ or ^~	reduction XNOR	reduction
+	unary (sign) plus	arithmetic
-	unary (sign) minus	arithmetic
{ }	concatenation	concatenation
{ { } }	replication	replication
*	multiply	arithmetic
/	divide	arithmetic
%	modulus	arithmetic
+	binary plus	arithmetic
-	binary minus	arithmetic
<<	shift left	shift
>>	shift right	shift
>	greater than	relational
>=	greater than or equal to	relational
<	less than	relational
<=	less than or equal to	relational
==	case equality	equality
!=	case inequality	equality
&	bit-wise AND	bit-wise
^	bit-wise XOR	bit-wise
	bit-wise OR	bit-wise
&&	logical AND	logical
	logical OR	logical
?:	conditional	conditional

1. Arithmetic

There are five arithmetic operators in Verilog.

```

module Arithmetic (A, B, Y1, Y2, Y3, Y4, Y5);

    input [2:0] A, B;
    output [3:0] Y1;
    output [4:0] Y3;
    output [2:0] Y2, Y4, Y5;
    reg [3:0] Y1;
    reg [4:0] Y3;
    reg [2:0] Y2, Y4, Y5;

    always @(A or B)
    begin
        Y1=A+B;//addition
        Y2=A-B;//subtraction
        Y3=A*B;//multiplication
        Y4=A/B;//division
        Y5=A%B;//modulus of A divided by B
    end
endmodule

```

2. Sign

These operators simply assign a positive "+" or negative "-" sign to a singular operand. Usually no sign operators is defined, in which case the default "+" is assumed.

```
module Sign (A, B, Y1, Y2, Y3);
```

```
    input [2:0] A, B;
    output [3:0] Y1, Y2, Y3;
    reg [3:0] Y1, Y2, Y3;

    always @(A or B)
    begin
        Y1=+A/-B;
        Y2=-A/+B;
        Y3=A*-B;
    end
endmodule
```

3. Relational

Relational operators compare two operands and returns an indication of whether the compared relationship is true or false. The result of a comparison is either **0** or **1**. It is **0** if the comparison is false and **1** if the comparison is true.

```
module Relational (A, B, Y1, Y2, Y3, Y4);
```

```
    input [2:0] A, B;
    output Y1, Y2, Y3, Y4;
    reg Y1, Y2, Y3, Y4;

    always @(A or B)
    begin
        Y1=A<B;//less than
        Y2=A<=B;//less than or equal to
        Y3=A>B;//greater than
        if (A>B)
            Y4=1;
        else
            Y4=0;
    end
endmodule
```

4. Equality and inequality

Equality and inequality operators are used in exactly the same way as relational operators and return a true or false indication depending on whether any two operands are equivalent or not.

```
module Equality (A, B, Y1, Y2, Y3);
```

```
    input [2:0] A, B;
    output Y1, Y2;
    output [2:0] Y3;
    reg Y1, Y2;
    reg [2:0] Y3;
    always @(A or B)
    begin
        Y1=A==B;//Y1=1 if A equivalent to B
        Y2=A!=B;//Y2=1 if A not equivalent to B
        if (A==B)//parenthesis needed
            Y3=A;
        else
            Y3=B;
    end
endmodule
```

5. Logical

Logical comparison operators are used in conjunction with relational and equality operators as described in the relational operators section and equality and inequality operators section. They provide a means to perform multiple comparisons within a single expression.

```
module Logical (A, B, C, D, E, F, Y);
```

```
    input [2:0] A, B, C, D, E, F;
    output Y;
    reg Y;

    always @(A or B or C or D or E or F)
    begin
        if ((A==B) && ((C>D) || !(E<F)))
            Y=1;
        else
            Y=0;
    end
endmodule
```

6. Bit-wise

Logical bit-wise operators take two single or multiple operands on either side of the operator and return a single bit result. The only exception is the **NOT** operator, which negates the single operand that follows. Verilog does not have the equivalent of **NAND** or **NOR** operator, their function is implemented by negating the **AND** and **OR** operators.

```

module Bitwise (A, B, Y);

    input [6:0] A;
    input [5:0] B;
    output [6:0] Y;
    reg [6:0] Y;

    always @(A or B)
    begin
        Y(0)=A(0)&B(0); //binary AND
        Y(1)=A(1)|B(1); //binary OR
        Y(2)=!(A(2)&B(2)); //negated AND
        Y(3)=!(A(3)|B(3)); //negated OR
        Y(4)=A(4)^B(4); //binary XOR
        Y(5)=A(5)~^B(5); //binary XNOR
        Y(6)=!A(6); //unary negation
    end
endmodule

```

7. Shift

Shift operators require two operands. The operand before the operator contains data to be shifted and the operand after the operator contains the number of single bit shift operations to be performed. 0 is being used to fill the blank positions.

```

module Shift (A, Y1, Y2);

    input [7:0] A;
    output [7:0] Y1, Y2;
    parameter B=3; reg [7:0] Y1, Y2;

    always @(A)
    begin
        Y1=A<<B; //logical shift left
        Y2=A>>B; //logical shift right
    end
endmodule

```

8. Concatenation and Replication

The concatenation operator "{ , }" combines (concatenates) the bits of two or more data objects. The objects may be scalar (single bit) or vectored (multiple bit). Multiple concatenations may be performed with a constant prefix and is known as replication.

```

module Concatenation (A, B, Y);

    input [2:0] A, B;
    output [14:0] Y;
    parameter C=3'b011;
    reg [14:0] Y;

    always @(A or B)
    begin
        Y={A, B, (2{C}), 3'b110};
    end
endmodule

```

9. Reduction

Verilog has six reduction operators, these operators accept a single vectored (multiple bit) operand, performs the appropriate bit-wise reduction on all bits of the operand, and returns a single bit result. For example, the four bits of A are **AND**ed together to produce Y1.

```

module Reduction (A, Y1, Y2, Y3, Y4, Y5, Y6);

    input [3:0] A;
    output Y1, Y2, Y3, Y4, Y5, Y6;
    reg Y1, Y2, Y3, Y4, Y5, Y6;

    always @(A)
    begin
        Y1=&A; //reduction AND
        Y2=|A; //reduction OR
        Y3=~&A; //reduction NAND
        Y4=~|A; //reduction NOR
        Y5=^A; //reduction XOR
        Y6=~^A; //reduction XNOR
    end
endmodule

```

10. Conditional

An expression using conditional operator evaluates the logical expression before the "?". If the expression is true then the expression before the colon (:) is evaluated and assigned to the output. If the logical expression is false then the expression after the colon is evaluated and assigned to the output.

```

module Conditional (Time, Y);

    input [2:0] Time;
    output [2:0] Y;
    reg [2:0] Y;

```

```
parameter Zero =3b'000;
parameter TimeOut = 3b'110;

always @(Time)
begin
    Y=(Time!=TimeOut) ? Time +1 : Zero;
end
endmodule
```
